

Introduction to strings

→ A string is a collection of characters enclosed in quotes

eg: name = "Coding Kannadiga"

Types.

i. single quotes:

s = 'Hello'

ii. Double quotes:

s = "Hello"

iii. Triple Quotes:

s = '''Hello

World'''

Note:

* Strings are ordered

* Strings are immutable

Questions:

1. Create a string and print it

2. Print a sentence using variables

String Indexing and Slicing

i. String Indexing:

→ Accessing characters using position

syntax:

var[index no] string[index no]

Note:

→ Negative Indexing refers to accessing characters from reverse.

ii. String Slicing:

→ get a part of string

syntax:

string[start: end]

* end is excluded

Step in slicing:

* used to jump value

Questions:

1. Print last 3 characters
2. print string in reverse
3. Print middle character,

String Methods

1. upper()

→ convert string to uppercase

2. lower()

→ convert string to lowercase

3. strip()

→ remove spaces

4. replace()

→ replace word

5. split()

→ split the string

6. find()

→ find position

7. count()

→ count characters

8.

Questions:

1. Find the position of occurrence of 'g' in programming
2. remove all spaces from a string "python"
3. Count vowels in a string "python programming"

STRING FORMATTING

→ String formatting is used to insert values into a string

Syntax:

f"string {variable}"

Why f string is best

- Clean
- Readable
- Fast

Decimal Formatting

→ $\pi = 3.14159$
print(f" π :.2f")

Old Format

→ Print("My name is {}".format(name, age))

Quiz:

→ Create a String using f-string to display your name in the format.

Practice Set:

1. Reverse the order of words in a sentence
"I love Python" $\rightarrow$ "Python love I"
2. Remove all vowels from the string
"faldinarvynitde"
3. Count the number of words in a sentence
"faldinarvynitde"
4. Find the most frequent character in a string
"faldinarvynitde"
5. Remove all frequent characters from a string.
"faldinarvynitde"
